Abstract: This paper is concerned to present design conditions for state-derivative feedback control for Takagi-Sugeno fuzzy descriptor models. The main contribution is to derive a PDC control law without the requirement to rewrite the fuzzy model to fit in some specific format. We propose sufficient conditions as Linear Matrices Inequalities with or without the decay rate constraint in the trajectories, assuming that all eigenvalues of the fuzzy plant models are not-null. Three examples illustrate the effectiveness the proposed conditions to derive gains for the state-derivative control law to stabilize nonlinear descriptor systems.

Keywords: Descriptor systems, Takagi-Sugeno models, State-derivative feedback, Linear Matrix Inequalities.

1. INTRODUCTION

As a matter of fact, descriptor systems have been investigated extensively since the seminal paper of Luenberger (1978) and, from the modeling point of view, this kind of system description (i.e., a differential algebraic system) arises naturally in a wide variety of real problems. We can cite the use of descriptor systems to modeling mechanical systems (Blandeau et al., 2018; Guelton et al., 2008), robots (Schulte and Guelton, 2009) and electrical circuits (Newcomb and Dziurla, 1989).

In the context of nonlinear systems, the Takagi-Sugeno fuzzy (T-S) modeling has become popular to represent nonlinear dynamics by a combination of linear systems (Tanaka and Wang, 2001). Nguyen et al., 2019 present a review about the history and point out the perspective of Fuzzy Control Systems. The first statement of T-S descriptor fuzzy system was made in Taniguchi et al. (1999) and its results were extended in Taniguchi et al. (2000).

In some practical situations, the state-derivative is easier to obtain than the state signals (Faria et al., 2010b). Abdelaziz and Valášek (2004) presented pole-placement technique for state-derivative feedback in SISO linear systems. Faria et al. (2009) presented LMI conditions to design a state-derivative feedback for linear multi-variable systems. In da Silva et al. (2011) the work of Faria et al. (2007), which presented LMI conditions to design stabilizing control T-S fuzzy standard systems, is generalized to uncertain T-S fuzzy standard systems. Further Kaewpraek

and Assawinchaichote (2017) added the H_∞ performance. Moreover, Faria et al. (2010a) dealt with state-derivative feedback in descriptor systems subject to structural failures in the plant.

A survey about derivative feedback control for descriptor systems is given by Junchao et al. (2006), which stated that the derivative feedback could change the derivative matrix for regularizing and controlling purposes. However, to the best of the authors knowledge, the stabilization problem for T-S fuzzy descriptor models using state-derivative feedback has not been investigated fully up to now.

The main purpose of this paper is to propose new LMI conditions for the design of a PDC (Parallel distributed Compensation) control law with a state-derivative feedback to improve the stabilization of T-S fuzzy descriptor models. The main idea is to achieve better performance in some sense for the nonlinear closed-loop system.

The paper is organized as follows: in Section 2 is presented the notation and the theoretical foundation around the technique of state-derivative feedback presented in Section 3. In order to show the effectiveness of the proposed controller design, numerical application examples are presented in Section 4. Finally, Section 5 concludes this work.

2. PRELIMINARIES AND NOTATION

Consider the following continuous-time controllable nonlinear descriptor model of the form:

$$E(x(t)) \dot{x}(t) = A(x(t))x(t) + B(x(t))u(t) \quad (1)$$

where $x(t) = [x_1, \dots, x_n]^T \in \mathbb{R}^n$ is the descriptor vector, $u(t) = [u_1, \dots, u_m]^T \in \mathbb{R}^m$ is the input vector, $E(x(t)) \in \mathbb{R}^{n \times n}$, $A(x(t)) \in \mathbb{R}^{n \times n}$ and $B(x(t)) \in \mathbb{R}^{n \times m}$. The uniqueness and existence of solutions for system $(E(x(t)), A(x(t)), B(x(t)))$ is guaranteed if $\det(\lambda E - A) \neq 0$ for some $\lambda \in \mathbb{C}$ and, then the pair (E, A) is called regular (Dai, 1989). The existing solution is impulsive-free if $\deg(\det(\lambda E - A)) = \text{rank}(E)$, for any initial condition. The system (1) could be represented by the following T-S fuzzy model defined in Taniguchi et al. (2000):

$$\sum_{k=1}^{r_e} v_k(z(t)) E_k \dot{x}(t) = \sum_{i=1}^{r_a} h_i(z(t)) (A_i x(t) + B_i u(t)) \quad (2)$$

where $E_k \in \mathbb{R}^{n \times n}$, $A_i \in \mathbb{R}^{n \times n}$ and $B_i \in \mathbb{R}^{n \times m}$ are constant matrices. $z(t)$ is the vector of premise variables and each $v_k(z(t))$ and $h_i(z(t))$ is a membership function (MF) ensuring the following convex-sum property:

$$\begin{aligned} v_k(z(t)) &> 0, & \sum_{k=1}^{r_e} v_k(z(t)) &= 1 \\ h_i(z(t)) &> 0, & \sum_{i=1}^{r_a} h_i(z(t)) &= 1 \end{aligned}$$

In order to simplify the notation, we rewrite (2) as:

$$E_v \dot{x} = A_h x + B_h u \quad (3)$$

where

$$\begin{aligned} A_h &= \sum_{i=1}^{r_a} h_i(z(t)) A_i & B_h &= \sum_{i=1}^{r_a} h_i(z(t)) B_i \\ E_v &= \sum_{k=1}^{r_e} v_k(z(t)) E_k \end{aligned}$$

This work is intended to find constant matrices $K_{ik} \in \mathbb{R}^{m \times n}$ with $i = 1, \dots, r_a$ and $k = 1, \dots, r_e$ to compute a PDC control law of the form

$$u(t) = - \sum_{i=1}^{r_a} \sum_{k=1}^{r_e} h_i(z) v_k(z) K_{ik} \dot{x}(t) = -K_{vh} \dot{x} \quad (4)$$

such that such (2) with the PDC control law in (4) given by:

$$\begin{aligned} E_v \dot{x} &= A_h x(t) - B_h K_{vh} \dot{x} \Rightarrow \\ \dot{x} &= (E_v + B_h K_{vh})^{-1} A_h x \end{aligned} \quad (5)$$

be regular, impulsive-free, asymptotically stable and the following condition holds:

$$\det(E_k + B_i K_{jk}) \neq 0, \quad (6)$$

for $i, j \in \{1, \dots, r_a\}$ and $k \in \{1, \dots, r_e\}$. We suppose that the matrices A_i with $i = 1, \dots, r_a$ are nonsingular ($\det(A_i) \neq 0, \forall i$). From this point, the time t , argument of the signals, and the premise variable z of the MF, is omitted.

Remark 1. According with Duan et al. (1999) its assured that $(E + BK)$ is a nonsingular matrix only if:

$$\text{rank}[E, B] = n \quad (7)$$

2.1 Useful Results

Consider a controllable linear descriptor system of the form

$$E \dot{x} = Ax + Bu \quad (8)$$

and a linear state-derivative feedback control law given as

$$u = -K \dot{x} \quad (9)$$

with $K \in \mathbb{R}^{m \times n}$. Assuming that $(E + BK)$ is nonsingular, the closed-loop of the system (8) with (9) can be written as

$$\dot{x} = (E + BK)^{-1} Ax(t) \quad (10)$$

In this way, the following theorem, based on a quadratic Lyapunov function, is very useful.

Theorem 2. (Faria et al., 2010a). Assuming that (7) holds, a necessary and sufficient condition to the system (10) be globally asymptotically stable is the existence of matrices $Q = Q^T \in \mathbb{R}^{n \times n}$ and $Y \in \mathbb{R}^{m \times n}$ such that:

$$AQE^T + EQA^T + BYA^T + AY^T B^T < 0 \quad (11a)$$

$$Q > 0 \quad (11b)$$

with the state-derivative feedback matrices are given by:

$$K = YQ^{-1} \quad (12)$$

Proof. See Faria et al. (2010a). $\square$

The Theorem 2 guarantees that if $\det(A_i) \neq 0, \forall i$, A_h is nonsingular (Faria et al., 2010b).

3. MAIN RESULTS

Based on Theorem 2 we can state the following:

Theorem 3. The T-S fuzzy descriptor system in (5) is regular, impulsive-free and asymptotically stable, if there exist a positive-definite matrix $Q \in \mathbb{R}^{n \times n}$ and matrices $Y_{jk} \in \mathbb{R}^{m \times n}$ such that the following LMIs are satisfied for $i, j, l \in \{1, \dots, r_a\}$ and $k \in \{1, \dots, r_e\}$:

$$E_k Q A_l^T + A_l Q E_k^T + B_i Y_{jk} A_l^T + A_l Y_{jk}^T B_i^T < 0 \quad (13)$$

and the state-derivative feedback matrix is given by:

$$K_{jk} = Y_{jk} Q^{-1} \quad (14)$$

Proof. Considering the convex-sum property of the MF, follows from (13) that:

$$\begin{aligned} \sum_{i,j,l=1}^{r_a} h_i h_j h_l \sum_{k=1}^{r_e} v_k [E_k Q A_i^T + A_i Q E_k^T + B_i Y_{jk} A_l^T + A_l Y_{jk}^T B_i^T] = \\ = E_v Q A_h^T + A_h Q E_v^T + B_h Y_{vh} A_h^T + A_h Y_{vh}^T B_h^T < 0 \end{aligned}$$

where

$$Y_{vh} = \sum_{j=1}^{r_a} \sum_{k=1}^{r_e} h_j v_k Y_{jk} \quad (15)$$

Thus, we have the same condition of Theorem 2, with $E = E_v$, $A = A_h$, $B = B_h$ and $Y = Y_{vh}$. Therefore, the existence of matrices Q and Y_{jk} such that (13) holds is a sufficient condition for the asymptotically stability of system (5). $\square$

Notice that the proposed LMI conditions do not require to rewrite the T-S fuzzy descriptor model unlike the approach proposed in Taniguchi et al. (2000) and directly do not derive matching conditions in results (Taniguchi et al. (1999)). In these designs, have the derivative matrix a singular derivative E in the closed-loop fuzzy model, which implies the necessity to prove the regularity and the exemption impulsive responses.

The reason for not needing to rewrite the model for the control design in our approach is because the state-derivative feedback regularizes the derivative matrix of the closed-loop system as can be seen in (5).

According with Boyd et al. (1994), the decay rate is defined as the largest γ such that:

$$\lim_{t \rightarrow \infty} e^{\gamma t} \|x(t)\| = 0 \quad (16)$$

holds for all trajectories of x . Using the quadratic Lyapunov function to establish a lower bound on the decay rate, we have:

$$\dot{V}(x) < -2\gamma V(x) \quad (17)$$

where $V(x) = x^T P x$.

Thus, we can state the following theorem:

Theorem 4. The T-S fuzzy descriptor system in (5) is regular, impulsive-free and asymptotically stable with a decay rate (16) greater to $\gamma > 0$, if there exist a positive-definite matrix $Q \in \mathbb{R}^{n \times n}$ and matrices $Y_{jk} \in \mathbb{R}^{m \times n}$ such that the following LMIs are satisfied for $i, j, l \in \{1, \dots, r_a\}$ and $k \in \{1, \dots, r_e\}$:

$$\begin{bmatrix} E_k Q A_l^T + A_l Q E_k^T + B_i Y_{jk} A_l^T + A_l Y_{jk}^T B_i^T \\ Q E_k^T + Y_{jk}^T B_i^T \\ E_k Q + B_i Y_{jk} \\ -\frac{Q}{2\gamma} \end{bmatrix} < 0 \quad (18)$$

and the state-derivative feedback matrices are given by:

$$K_{jk} = Y_{jk} Q^{-1} \quad (19)$$

Proof. By (17) and computing $\dot{V}$ we have:

$$\begin{aligned} \dot{V}(x) &= x^T A_h^T (E_v + B_h K_{hv})^{-T} P x + x^T P (E_v + \\ &\quad B_h K_{hv})^{-1} A_h x < -2\gamma x^T P x \Rightarrow \\ &A_h^T (E_v + B_h K_{hv})^{-T} P + P (E_v + B_h K_{hv})^{-1} A_h < \\ &\quad -2\gamma P \quad (20) \end{aligned}$$

where M^{-T} means the transpose of M^{-1} .

Pre and post-multiplying (20) by $(E_v + B_h K_{hv})P^{-1}$ and $P^{-1}(E_v + B_h K_{hv})^T$, respectively, and applying the convex-sum property of MF and the Schur complements (Boyd et al., 1994) we obtain:

$$\begin{bmatrix} E_k P^{-1} A_i^T + A_i P^{-1} K_{jk}^T B_i^T + A_i P^{-1} E_k^T + B_i K_{jk} P^{-1} A_l^T \\ P^{-1} E_k^T + P^{-1} K_{jk}^T B_i^T \\ E_k P^{-1} + B_i K_{jk} P^{-1} \\ -\frac{P^{-1}}{2\gamma} \end{bmatrix} < 0$$

Defining $Q = P^{-1}$ and $Y_{jk} = K_{jk} P^{-1}$, then it follows the LMI condition (18). Therefore, given a $\gamma > 0$, the existence of matrices Q and Y_{jk} such that (18) holds is a sufficient condition for the asymptotically stability of system (5) with a decay rate greater than γ . $\square$

4. NUMERICAL EXAMPLES

The numerical examples were simulated using Matlab. The computational implementations of the LMI conditions have been carried out using as parser and solver, YALMIP and Mosek 8, respectively.

4.1 Example 1

Consider the following system from Taniguchi et al. (2000) which nonlinear dynamics described by:

$$(1 + a \cos(\theta(t)))\ddot{\theta}(t) = -b\dot{\theta}^3(t) + c\theta(t) + du(t) \quad (21)$$

where it is assumed that $a < 1$ and $|\dot{\theta}(t)| < \phi$. We use $a = 0.2$, $b = 1$, $c = -1$, $d = 10$ and $\phi = 4$. The nonlinear

system in (21) can be exactly represented by the following fuzzy descriptor system:

$$\sum_{k=1}^2 v_k(x_1(t)) E_k \dot{x} = \sum_{i=1}^2 h_i(x_2(t)) (A_i x(t) + B_i u(t)) \quad (22)$$

where $x(t) = [x_1(t) \ x_2(t)]^T = [\theta(t) \ \dot{\theta}(t)]^T$,

$$\begin{aligned} E_1 &= \begin{bmatrix} 1 & 0 \\ 0 & 1+a \end{bmatrix}, & E_2 &= \begin{bmatrix} 1 & 0 \\ 0 & 1-a \end{bmatrix}, \\ A_1 &= \begin{bmatrix} 0 & 1 \\ c & -b\phi^2 \end{bmatrix}, & A_2 &= \begin{bmatrix} 0 & 1 \\ c & 0 \end{bmatrix}, \\ B_1 &= B_2 = \begin{bmatrix} 0 \\ d \end{bmatrix} \end{aligned}$$

and the membership functions

$$\begin{aligned} h_1(x_2) &= \frac{x_2^2}{\phi^2} & h_2(x_2) &= 1 - h_1(x_2) \\ v_1(x_1) &= \frac{1 + \cos(x_1)}{2} & v_2(x_1) &= 1 - v_1(x_1) \end{aligned}$$

Notice that the derivative matrices, E_1 and E_2 , are regular and positive definite.

Applying Theorem 3, we find that the LMIs condition are feasible with:

$$Q = \begin{bmatrix} 0.2627 & -0.0314 \\ -0.0314 & 1.0037 \end{bmatrix}$$

$$Y_{11} = Y_{21} = [0.1048 \ -0.1207]$$

$$Y_{12} = Y_{22} = [0.1035 \ -0.0805]$$

and the PDC control gains in (4) are calculated using (14):

$$K_{11} = K_{12} = [0.3860 \ -0.1082]$$

$$K_{21} = K_{22} = [0.3860 \ -0.0682] \quad (23)$$

Figure 1 depicts the trajectories of the states and the input control of the closed-loop system with (4) (with gain given in (23)) and the exact model in (21), that is, using the original system for the simulation not the T-S fuzzy model in (22). Notice that the T-S fuzzy model in (22) was used only to compute the control gains via Theorem 3. In this case we intend to show the effectiveness of the PDC control design proposed, i.e., the PDC controller is tested to control directly the original system in (16), without any kind of approximation. In Figure 1 was used as initial condition $x_0 = [2 \ -0.5]^T$.

4.2 Example 2

The system in (21) can also be exactly represented by the following fuzzy descriptor form given in Lin et al. (2006):

$$E \dot{x} = \sum_{i=1}^3 h_i(x(t)) (A_i x(t) + B_i u(t)) \quad (24)$$

where $x(t) = [x_1(t) \ x_2(t) \ x_3(t)]^T = [\theta(t) \ \dot{\theta}(t) \ \ddot{\theta}(t)]^T$

$$\begin{aligned} E &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} & A_1 &= \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ c & -b(\phi^2 + 2) & (a-1) \end{bmatrix} \\ A_3 &= \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ c & 0 & (a-1) \end{bmatrix} & A_2 &= \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ c & 0 & (-a-1-a\phi^2) \end{bmatrix} \\ B_1 &= B_2 = B_3 = \begin{bmatrix} 0 \\ 0 \\ d \end{bmatrix} \end{aligned}$$

Figure 1. Trajectories for the closed-loop system with (21) - the original nonlinear system - and the state-derivative feedback as in (4) with gain obtained in (23) for initial condition $x_0 = [2 \ -0.5]^T$. Example 1.

and the MF are defined as following:

$$h_1 = \frac{x_2^2}{\phi^2 + 2} \quad h_2 = \frac{1 + \cos(x_1)}{\phi^2 + 2}$$

$$h_3 = \frac{\phi^2 - x_2^2 + 1 - \cos(x_1)}{\phi^2 + 2}$$

holding the convex-sum property. Notice that the derivative matrix is singular and the condition given in Remark 1 holds.

Applying the conditions stated in Theorem 3, we get the following solution

$$Q = \begin{bmatrix} 0.2251 & -0.0271 & -0.0262 \\ -0.0271 & 0.0208 & -0.1645 \\ -0.0262 & -0.1645 & 2.3286 \end{bmatrix}$$

$$Y_{11} = Y_{21} = Y_{31} = [0.1562 \quad -0.0002 \quad 0.0117]$$

which results the PDC control gains for (4) using (14):

$$K_{11} = K_{21} = K_{31} = [1.396 \quad 3.4638 \quad 0.2525] \quad (25)$$

The results of the simulation of (21) in closed-loop with control law (4) and gains given in (25) for initial condition $x_0 = [2 \ -0.5 \ -0.2227]^T$ are depicted in Figure 2. Following the same steps in Example 1, the T-S fuzzy model in (24) was used only to compute the state-derivative matrix via Theorem 3, but the simulation was performed using the original nonlinear system described in (21). In this case, the idea is to illustrate the effectiveness of the proposed approach, but ensuring condition stated in Remark 1, for the case when E is not full rank.

Figure 2. Trajectories for the closed-loop system with (21) - the original nonlinear system - and the state-derivative feedback as in (4) with gain obtained in (25) for initial condition $x_0 = [2 \ -0.5 \ -0.2227]^T$. Example 2.

4.3 Example 3

The third example is borrowed from Blandeau et al. (2016) to illustrate the effectiveness of the proposed approach in a system with $n = 4$. Consider a nonlinear system as in (1) where:

$$E(x) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & m_1 & 0 & -m_1 l_0 \\ 0 & 0 & 1 & 0 \\ 0 & -m_1 l_0 & 0 & J(x_l) \end{bmatrix}, \quad B(x) = \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix},$$

$$A(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & -m_1 g \frac{\sin \theta}{\theta} & m_1 x_l \dot{\theta} \\ 0 & 0 & 0 & 1 \\ -m_1 g \cos \theta & -2m_1 x_l \dot{\theta} \left(\frac{m_1 l_0}{m_2 l_c} \right) g \frac{\sin \theta}{\theta} & 0 & 0 \end{bmatrix} \quad (26)$$

with $J(x_l) = (m_1(l_0^2 + x_l^2) + m_2 l_c^2)$.

This model represents the dynamics of the H2AT (“head, two arms and trunk”) pendulum, that is an extended version of the planar inverted pendulum consisting of two rods and it is used to study sitting stability of persons with Spine Cord Injury (Blandeau et al., 2016).

The parameters are: $m_1 = 16.1\text{kg}$, $m_2 = 26.64\text{kg}$, $l_0 = 477\text{mm}$, $l_c = 276.66\text{mm}$, $g = 9.81\text{m/s}^2$. The operation ranges for the states of the system are presented in the following compact set:

$$\Omega = \left\{ \begin{array}{l} x_l = -0.07518 \leq x_l \leq 0.10527 = \bar{x}_l \\ \theta = -0.175 \leq \theta \leq 0.349 = \bar{\theta} \\ \dot{\theta} = -0.5 \leq \dot{\theta} \leq 0.5 = \bar{\dot{\theta}} \end{array} \right\} \quad (27)$$

Blandeau et al. (2018) propose to consider $\sin(\theta)/\theta \approx \cos(\theta)$ for the operational range presented in (27), then the H2AT can be approximately represented by:

$$\sum_{k=1}^2 v_k E_k \dot{x} = \sum_{i=1}^4 h_i A_i x(t) + Bu(t) \quad (28)$$

where

$$E_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 16.10 & 0 & -7.678 \\ 0 & 0 & 1 & 0 \\ 0 & -7.678 & 0 & 5.881 \end{bmatrix}, \quad E_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 16.10 & 0 & -7.678 \\ 0 & 0 & 1 & 0 \\ 0 & -7.678 & 0 & 5.702 \end{bmatrix},$$

$$A_1 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & -157.941 & 0.847 \\ 0 & 0 & 0 & 1 \\ -157.941 & -1.695 & 147.640 & 0 \end{bmatrix},$$

$$A_2 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & -157.941 & -0.847 \\ 0 & 0 & 0 & 1 \\ -157.941 & 1.695 & 147.640 & 0 \end{bmatrix},$$

$$A_3 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & -148.420 & 0.847 \\ 0 & 0 & 0 & 1 \\ -148.420 & -1.695 & 138.739 & 0 \end{bmatrix},$$

$$A_4 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & -148.420 & -0.847 \\ 0 & 0 & 0 & 1 \\ -148.420 & 1.695 & 138.739 & 0 \end{bmatrix}.$$

The MF h_i , $i = 1, 2, 3, 4$ are constructed with the following weighting functions (WF):

$$\begin{aligned} w_0^1 &= \frac{\cos(\theta) - \cos(\bar{\theta})}{\cos(0) - \cos(\bar{\theta})} & w_1^1 &= 1 - w_0^1 \\ w_2^0 &= \frac{x_l \dot{\theta} - \bar{x}_l \dot{\theta}}{\bar{x}_l \dot{\theta} - \bar{x}_l \dot{\theta}} & w_2^1 &= 1 - w_2^0 \end{aligned}$$

Thus we have as MF for (28):

$$\begin{aligned} v_1 &= \frac{x_l^2}{\bar{x}_l^2} & v_2 &= 1 - v_1 \\ h_1 &= w_0^1 w_2^0 & h_2 &= w_0^1 w_1^2 \\ h_3 &= w_1^1 w_2^0 & h_4 &= w_1^1 w_1^2 \end{aligned}$$

Applying Theorem 3 to the approximated model in (28), we obtain:

$$Q = \begin{bmatrix} 0.0011 & -0.0027 & 0.0012 & -0.0034 \\ -0.0027 & 0.0720 & -0.0030 & 0.0919 \\ 0.0012 & -0.0030 & 0.0016 & -0.0045 \\ -0.0034 & 0.0919 & -0.0045 & 0.1210 \end{bmatrix},$$

$$Y_{j1} = [0.0291 \quad -0.2915 \quad 0.0236 \quad -0.3494],$$

$$Y_{j2} = [0.0277 \quad -0.2892 \quad 0.0225 \quad -0.3436],$$

$$j \in \{1, 2, 3, 4\}$$

and the PDC control gains in (4) are calculated using (14):

$$K_{j1} = [2.1590 \quad 0.4881 \quad -1.8783 \quad -0.3798] \times 10^4,$$

$$K_{j2} = [1.6592 \quad 0.3747 \quad -1.4433 \quad -0.2916] \times 10^4, \quad (29)$$

$$j \in \{1, 2, 3, 4\}$$

Applying Theorem 4 with $\gamma = 1$ to the approximated model in (28), that LMIs condition are feasible with:

$$Q = \begin{bmatrix} 0.0004 & -0.0011 & 0.0004 & -0.0012 \\ -0.0011 & 0.0200 & -0.0011 & 0.0252 \\ 0.0004 & -0.0011 & 0.0006 & -0.0019 \\ -0.0012 & 0.0252 & -0.0019 & 0.0350 \end{bmatrix},$$

$$Y_{j1} = [0.0302 \quad -0.1539 \quad 0.0281 \quad -0.1704],$$

$$Y_{j2} = [0.0273 \quad -0.0918 \quad 0.0243 \quad -0.0881],$$

$$j \in \{1, 2, 3, 4\}$$

and the PDC control gains in (4) are calculated using (19):

$$K_{j1} = [1.5016 \quad 0.3213 \quad -1.2602 \quad -0.2526] \times 10^3,$$

$$K_{j2} = [1.5935 \quad 0.3438 \quad -1.3395 \quad -0.2675] \times 10^3, \quad (30)$$

$$j \in \{1, 2, 3, 4\}$$

Figure 3 depicts the trajectories of the states and the input control of the closed-loop system with the PDC control law as in (4) with gains given in (29) and in (30). It is clear that the trajectories of controller with gain (30) have a faster transient response, because it is imposed a bound in decay rate in Theorem 4.

Figure 3. Trajectories for the closed-loop system as in (2) with (26), represented in the design by (28), with the derivative-state feedback as in (4) and gains given in (29) (Thm 3) and (30) (Thm 4) for initial condition $x_0 = [-0.01 \quad 0.02 \quad 0 \quad -0.01]^T$. Example 3.

5. CONCLUSION

This paper has proposed LMI conditions to design a PDC control law based on state-derivative feedback. These conditions require the eigenvalues of matrix A are not null but it is not necessary to rewrite the system to design the controller. Numerical examples have been presented to illustrate the utility of the proposed method under different types of nonlinear descriptor models. We can cite as open problems for future works, the development of more relaxed conditions and its application in delayed T-S fuzzy descriptor systems.
