Abstract

Vitamin D3 deficiency is associated with an increased risk of multiple sclerosis (MS) and unfavorable MS disease progression. Here we demonstrated immunomodulatory effect of vitamin D in Experimental autoimmune encephalomyelitis a experimental model for studying MS.

Key words: *multiple sclerosis, vitamin D, EAE.*

Introduction

EAE is an antigen-driven autoimmune model in which immunization against myelin autoantigens elicits strong CD4 T lymphocyte responses, which initiate its pathology with central nervous system myelin destruction. Material and Methods: EAE was induced by immunization with MOG35- 55 peptide emulsified in complete Freund adjuvant. The clinical expression of the disease was graded on a clinical scale 0-5 according to the severity of the disease. Vitamin D3 (cholecalciferol D3) Sigma Aldr. Mo, USA) was diluted in polyethylene glycol and give orally (5µg/Kg/day) during 2 weeks. The control group was fed with vehicle alone (15 animal/group were studied in three independent experiments. The expression of cytokine mRNA was evaluated by quantitative RT-PCR.

Results and Discussion

We demonstrated that the oral administration of vitamin D reduced significantly the severity of EAE. The reduction of the severity of the disease was accompanied by the reduction of proinflammatory cytokines such as IFNγ and increase of antiinflammatory cytokines such as IL-10 and IL-27

Score Analysis Charts

Results Real Time PCR

Score is the technique used to measure the animal's Disease.

Conclusions

We conclude that vitamin D3 present immunomodulatory effect in the EAE model. The immunosuppressive mechanism may inhibit the migration of autoreactive T lymphocytes into central nervous system. Moreover, the study suggest that supplementation with vitamin D3 may be beneficial to patients with multiple sclerosis, that present a functional vitamin D receptor.
