Abstract

The relationship between human papillomavirus and head and neck cancers has been demonstrated in the literature, and this study aims to demonstrate the prevalence of this virus in head and neck cancers of twenty-seven adults and elderly patients attended in the hospital of clinics Unicamp Campinas, in 2014.

Key words: Human papillomavirus, head and neck cancer, elderly.

Introduction

Virus has been associated as causative agents for a large proportion of various human malignancies¹. The oncogenic potential of *human papillomavirus* (HPV) and its possible role in the development of malignant conditions, in particular cancer of head and neck has been described. This study evaluated the presence of HPV DNA in fresh biopsies of tissues surgically removed of twenty-seven adults and elderly patients, aged 45 to 75 years.

Results and Discussion

Fresh biopsies from 16 patients with head and neck cancer and 11 fresh biopsies from a healthy control group were studied. DNA extraction was made and nested PCR technique was used for DNA detection in lesions.

HPV occurred in 8/16 (50%) cancer biopsies and only one patient in control group was positive (9,1%).

Worldwide, cancer centers report that virus is responsible for between 45% and 90% of oropharyngeal cancers². According to a meta-analysis conducted by the University of Birmingham, UK, oropharyngeal cancer (OPC) associated with HPV quadrupled in number over a period of 10 to 15 years. In contrast, the relatively low prevalence of HPV in non-OPC remains unchanged³. More than 90% of HPV-related oropharyngeal cancers are caused by HPV-16, a particularly dangerous strain and the main cause of cervical cancer. In other study, D'Souza *et al.*⁴ showed the association was similarly increased among subjects with oral HPV-16 infection, regardless of their tobacco and alcohol use. By contrast, tobacco and alcohol use increased the association with oropharyngeal cancer primarily among subjects without exposure to HPV-16. Oral HPV infection is strongly associated with oropharyngeal cancer among subjects with or

without the established risk factors of tobacco and alcohol use.

Chart 1. Positive and negative samples of fresh tissue of the groups of head and neck cancer and control, using the technique of nested-PCR for the detection of human papillomavirus DNA.

Groups	Positive samples	Negative samples
Cancer group (n=16)	8	8
Control group (n=11)	1	10
p-value	0,0417	

Fischer's test: p-value <0,005 – 95% CI.

Conclusions

HPV is related to the development of head and neck cancer, and our study found a higher prevalence in subjects in the cancer group compared to the control group, corroborating with the findings of other authors.
